1 Introduction (by Jeremy J. SAVILL)

In 2006 one of us (J.J.S.) found a single partly crushed specimen of the flexible crinoid *Ammonicrinus* in the Middle Devonian strata of the Cantabrian Mountains of northern Spain.

Schlüsselwörter: *Ammonicrinus*, Crinoidea, Flexibilia, Systematik, Kantabrisches Gebirge, Nordspanien, Portilla Formation, Givetium.

Key-words: *Ammonicrinus*, Crinoidea, Flexibilia, Systematic, Cantabrian Mountains, Northern Spain, Portilla Formation, Givetian.

Zusammenfassung: Mit diesem Aufsatz wird der Erstnachweis von *Ammonicrinus* im Kantabrischen Gebirge geführt. Das Verbreitungsgebiet von *Ammonicrinus* liegt sowohl im westlichen, mittleren als auch im südlichen Europa.

Abstract: This paper documents the first finding of this genus in the Cantabrian Mountains. The Spanish occurrence of *Ammonicrinus* expands the record of the genus from Central Europe (Germany) into Western Europe.

2 Stratigraphy of the section of Barrios de Gordón (by Fernando Gómez Landeta in HAUSER & LANDETA, 2007:19-20)

2.1 Locality

The specimen was found on a steep slope (near the outcrops in Figure 1) above the eastern side of road (N-630), about 500m to the

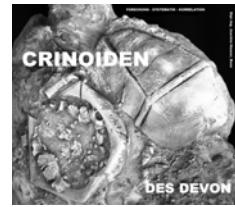

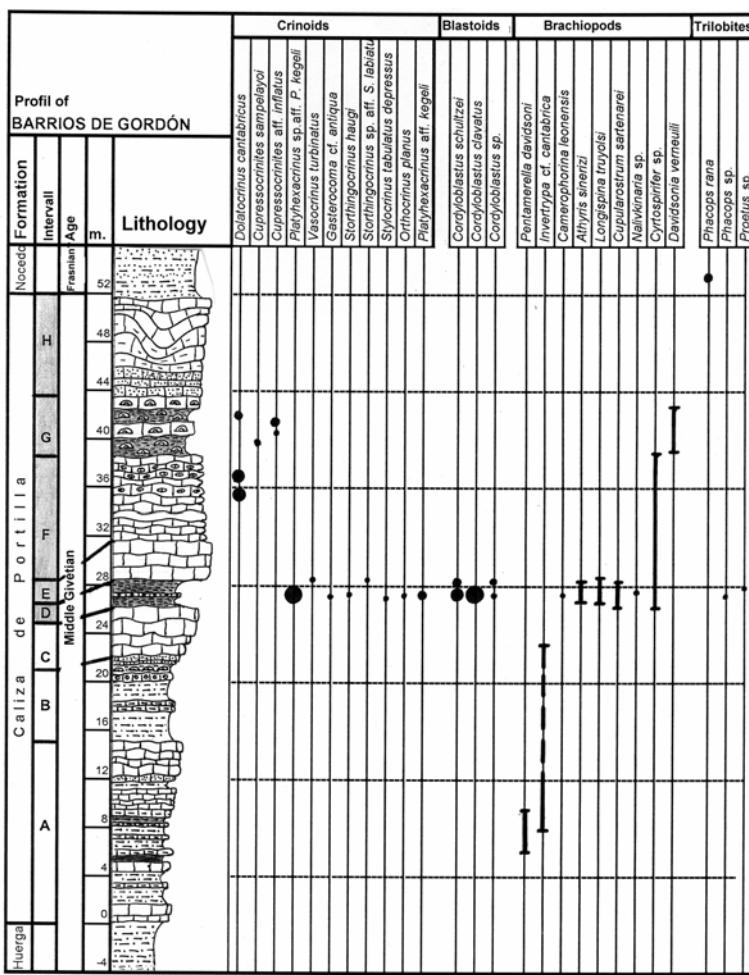

south of Huergas de Gordón (Geological 1:50.000 map 103, 13-7. Grid reference 43829169). The stratigraphy and general fauna of this locality was described ALCALDE et al., 1979.

← Figure 2: Age and correlation of the Devonian Formations in the Cantabrian Area, with the crinoid levels cited in BREIMER, 1962 and HAUSER & LANDETA, 2007

2.2 Stratigraphy

A good section can be obtained of the formation in different points along the slope of the EW-hill (Fig. 1). The lower part rests conformably over the deep water shales of the Huergas formation (Fig. 2). The lower 25 metres of which is a shallowing upward succession with branching coral colonies living in a mud environment, and which culminates in a reefal Packestone. After a deepening of the basin the rest of the section is a new regressive, shallowing upward succession, culminated by a small biostrome. The sequence is capped by 2-3 metres of recrystallized grainstones. In an erosive contact with, this facies shows spectacular examples of slumps which can be interpreted as a channel which links the tidal lagoon to the North with the open basin to the South, cutting through the small reefal barrier.

← Figure 3: Stratigraphic column for the section of Barrios de Gordón.

2.3 Paleontology

The section is very fossiliferous, the brachiopods, corals and trilobites found and their ranges of existence are shown in figure 3. Notably fossiliferous is the small mudstone interval. All the fauna especially the brachiopods have a marked Givetian character. *Ammonicrinus* was found in the upper half of the section and is below.

2.4 Age

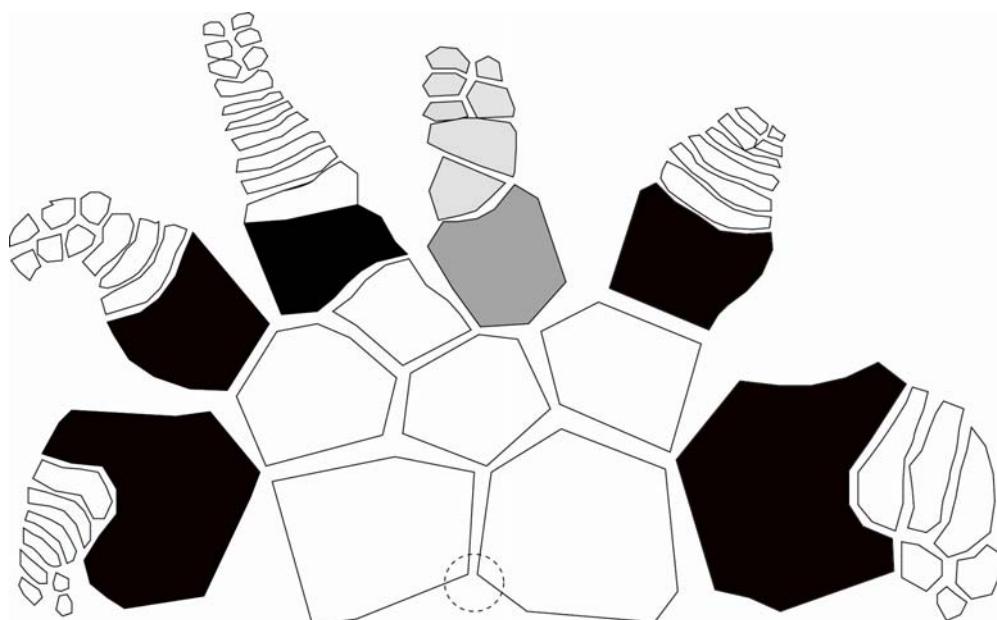

With reference to the ALCALDE et al., 1979, the Barrios section can be aged as Middle Givetian. In fact, in Huergas the conodonts allow the strata to be established as lower and middle *varcus* subbiozones (ISC) in all the exposed outcrops of the formation except its last metres which are already in the *hermanni* – *cristatus* zone. Lithologically, unit A of GARCÍA ALCALDE et al., 1979

can be correlated with unit on beds (A-B-C-D), in Barrios, and their unit B, with unit on beds (E-F-G). It is remarkable the difference in the thickness of the biostromal upper term in both sections, 13m in Huergas (terms 18b – 22), and merely 5m (G), in Barrios, due to the difference caused by the erosion of the channel mentioned above.

3 Systematics (by Joachim HAUSER)

Classe Crinoidea J. S. MILLER, 1821
Subclasse Flexibilia ZITTEL, 1895
Order Sagenocrinida SPRINGER, 1913
Superfamily Lecanocrinacea SPRINGER, 1913
Family Calycocrinidae MOORE & STRIMPLE, 1973
Genus *Ammonicrinus* SPRINGER, 1926

Typ-species: *Ammonicrinus doliformis*

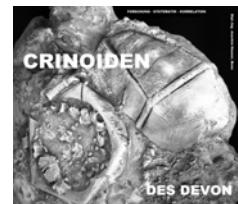

Stratigraphical distribution:
Middle Devonian

Material: One specimen from the Portilla Formation, Givetian of Northern Spain; more than 20 more or less complete specimens from the Ahbach Formation, Givetian of the Prüm Synclinorium of the Rhenish-Slate-Mountains and 5 specimens from the Hillesheim Synclinorium (Nollenbach and Steineberg section), Freilingen Formation, Eifelium.

← ↑ Figure: 5-7: *Ammonicrinus wanneri* from the section of Barrios de Gordón

Description: A typical formed partly damaged and weathered *Ammonicrinus wanneri*. Specimen more or less elliptical, with coiled stem, proximal part of the columnals throughout midlength of stem strongly arched with transverse ridge. The surface of the specimen has small rounded tubercles. The single columnals are smooth from the middle of the hook to the distal side and they are uneven in form and dimension. The centre of the specimen shows only a very poorly preserved part of the calyce / crown. The distal part of the stem is not preserved.

Dimensions: max. length = 2,5 cm; max. hight = 1,6 cm.

Stratigraphical and geographical distribution: *Ammonicrinus wanneri* is more or less common in the Nollenbach Member of the Freilingen Formation (Eifelian) (Hillesheim synclinorium) and in the ?Olifant Member of the Ahbach Formation (Givetian) (Prüm Synclinorium) of the Eifel-Hills (Rhenish Slate Mountains). The specimen we described here was collected in the Portilla Formation, Middle Givetian, of the Cantabrian Mountains, Province Leon, Northern Spain.

Other fossils of the outcrop: An overall view of the fossils in the section of Barrios de Gordón is shown in figure 3.

Acknowledgements: Our special thanks go to Fernando Gómez LANDETA, Oviedo, who wrote the stratigraphical part of this paper and Dr. Gary WEBSTER who reviewed the typescript.
